

# NAG Library Function Document

## nag\_zggbal (f08wvc)

### 1 Purpose

nag\_zggbal (f08wvc) balances a pair of complex square matrices  $(A, B)$  of order  $n$ . Balancing usually improves the accuracy of computed generalized eigenvalues and eigenvectors.

### 2 Specification

```
#include <nag.h>
#include <nagf08.h>

void nag_zggbal (Nag_OrderType order, Nag_JobType job, Integer n,
                Complex a[], Integer pda, Complex b[], Integer pdb, Integer *i1o,
                Integer *ihi, double lscale[], double rscale[], NagError *fail)
```

### 3 Description

Balancing may reduce the 1-norm of the matrices and improve the accuracy of the computed eigenvalues and eigenvectors in the complex generalized eigenvalue problem

$$Ax = \lambda Bx.$$

nag\_zggbal (f08wvc) is usually the first step in the solution of the above generalized eigenvalue problem. Balancing is optional but it is highly recommended.

The term ‘balancing’ covers two steps, each of which involves similarity transformations on  $A$  and  $B$ . The function can perform either or both of these steps. Both steps are optional.

1. The function first attempts to permute  $A$  and  $B$  to block upper triangular form by a similarity transformation:

$$PAP^T = F = \begin{pmatrix} F_{11} & F_{12} & F_{13} \\ & F_{22} & F_{23} \\ & & F_{33} \end{pmatrix}$$

$$PBP^T = G = \begin{pmatrix} G_{11} & G_{12} & G_{13} \\ & G_{22} & G_{23} \\ & & G_{33} \end{pmatrix}$$

where  $P$  is a permutation matrix,  $F_{11}$ ,  $F_{33}$ ,  $G_{11}$  and  $G_{33}$  are upper triangular. Then the diagonal elements of the matrix pairs  $(F_{11}, G_{11})$  and  $(F_{33}, G_{33})$  are generalized eigenvalues of  $(A, B)$ . The rest of the generalized eigenvalues are given by the matrix pair  $(F_{22}, G_{22})$  which are in rows and columns  $i_{1o}$  to  $i_{hi}$ . Subsequent operations to compute the generalized eigenvalues of  $(A, B)$  need only be applied to the matrix pair  $(F_{22}, G_{22})$ ; this can save a significant amount of work if  $i_{1o} > 1$  and  $i_{hi} < n$ . If no suitable permutation exists (as is often the case), the function sets  $i_{1o} = 1$  and  $i_{hi} = n$ .

2. The function applies a diagonal similarity transformation to  $(F, G)$ , to make the rows and columns of  $(F_{22}, G_{22})$  as close in norm as possible:

$$DF\hat{D} = \begin{pmatrix} I & 0 & 0 \\ 0 & D_{22} & 0 \\ 0 & 0 & I \end{pmatrix} \begin{pmatrix} F_{11} & F_{12} & F_{13} \\ & F_{22} & F_{23} \\ & & F_{33} \end{pmatrix} \begin{pmatrix} I & 0 & 0 \\ 0 & \hat{D}_{22} & 0 \\ 0 & 0 & I \end{pmatrix}$$

$$DGD^{-1} = \begin{pmatrix} I & 0 & 0 \\ 0 & D_{22} & 0 \\ 0 & 0 & I \end{pmatrix} \begin{pmatrix} G_{11} & G_{12} & G_{13} \\ & G_{22} & G_{23} \\ & & G_{33} \end{pmatrix} \begin{pmatrix} I & 0 & 0 \\ 0 & \hat{D}_{22} & 0 \\ 0 & 0 & I \end{pmatrix}$$

This transformation usually improves the accuracy of computed generalized eigenvalues and eigenvectors.

## 5 Arguments

1: **order** – Nag\_OrderType *Input*

*On entry:* the **order** argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by **order** = Nag\_RowMajor. See Section 2.3.1.3 in How to Use the NAG Library and its Documentation for a more detailed explanation of the use of this argument.

*Constraint:* **order** = Nag\_RowMajor or Nag\_ColMajor.

2: **job** – Nag\_JobType *Input*

*On entry:* specifies the operations to be performed on matrices  $A$  and  $B$ .

**job** = Nag\_DoNothing

No balancing is done. Initialize **ilo** = 1, **ihi** = **n**, **lscale**[ $i - 1$ ] = 1.0 and **rscale**[ $i - 1$ ] = 1.0, for  $i = 1, 2, \dots, n$ .

**job** = Nag\_Permute

Only permutations are used in balancing.

**job** = Nag\_Scale

Only scalings are used in balancing.

**job** = Nag\_DoBoth

Both permutations and scalings are used in balancing.

*Constraint:* **job** = Nag\_DoNothing, Nag\_Permute, Nag\_Scale or Nag\_DoBoth.

3: **n** – Integer *Input*

*On entry:*  $n$ , the order of the matrices  $A$  and  $B$ .

*Constraint:* **n**  $\geq$  0.

4: **a**[ $dim$ ] – Complex *Input/Output*

**Note:** the dimension,  $dim$ , of the array **a** must be at least  $\max(1, pda \times n)$ .

Where  $\mathbf{A}(i, j)$  appears in this document, it refers to the array element

$\mathbf{a}[(j - 1) \times pda + i - 1]$  when **order** = Nag\_ColMajor;  
 $\mathbf{a}[(i - 1) \times pda + j - 1]$  when **order** = Nag\_RowMajor.

*On entry:* the  $n$  by  $n$  matrix  $A$ .

*On exit:* **a** is overwritten by the balanced matrix. If **job** = Nag\_DoNothing, **a** is not referenced.

5: **pda** – Integer *Input*

*On entry:* the stride separating row or column elements (depending on the value of **order**) in the array **a**.

*Constraint:* **pda**  $\geq$   $\max(1, n)$ .

6: **b**[ $dim$ ] – Complex *Input/Output*

**Note:** the dimension,  $dim$ , of the array **b** must be at least  $\max(1, pdb \times n)$ .

Where  $\mathbf{B}(i, j)$  appears in this document, it refers to the array element

$$\begin{aligned} &\mathbf{b}[(j-1) \times \mathbf{pdb} + i - 1] \text{ when } \mathbf{order} = \text{Nag\_ColMajor}; \\ &\mathbf{b}[(i-1) \times \mathbf{pdb} + j - 1] \text{ when } \mathbf{order} = \text{Nag\_RowMajor}. \end{aligned}$$

*On entry:* the  $n$  by  $n$  matrix  $B$ .

*On exit:*  $\mathbf{b}$  is overwritten by the balanced matrix. If  $\mathbf{job} = \text{Nag\_DoNothing}$ ,  $\mathbf{b}$  is not referenced.

7: **pdb** – Integer *Input*

*On entry:* the stride separating row or column elements (depending on the value of **order**) in the array  $\mathbf{b}$ .

*Constraint:*  $\mathbf{pdb} \geq \max(1, n)$ .

8: **ilo** – Integer \* *Output*

9: **ihi** – Integer \* *Output*

*On exit:*  $i_{lo}$  and  $i_{hi}$  are set such that  $\mathbf{A}(i, j) = 0$  and  $\mathbf{B}(i, j) = 0$  if  $i > j$  and  $1 \leq j < i_{lo}$  or  $i_{hi} < i \leq n$ .

If  $\mathbf{job} = \text{Nag\_DoNothing}$  or  $\text{Nag\_Scale}$ ,  $i_{lo} = 1$  and  $i_{hi} = n$ .

10: **lscale[n]** – double *Output*

*On exit:* details of the permutations and scaling factors applied to the left side of the matrices  $A$  and  $B$ . If  $P_i$  is the index of the row interchanged with row  $i$  and  $d_i$  is the scaling factor applied to row  $i$ , then

$$\mathbf{lscale}[i-1] = P_i, \text{ for } i = 1, 2, \dots, i_{lo} - 1;$$

$$\mathbf{lscale}[i-1] = d_i, \text{ for } i = i_{lo}, \dots, i_{hi};$$

$$\mathbf{lscale}[i-1] = P_i, \text{ for } i = i_{hi} + 1, \dots, n.$$

The order in which the interchanges are made is  $n$  to  $i_{hi} + 1$ , then 1 to  $i_{lo} - 1$ .

11: **rscale[n]** – double *Output*

*On exit:* details of the permutations and scaling factors applied to the right side of the matrices  $A$  and  $B$ .

If  $P_j$  is the index of the column interchanged with column  $j$  and  $\hat{d}_j$  is the scaling factor applied to column  $j$ , then

$$\mathbf{rscale}[j-1] = P_j, \text{ for } j = 1, 2, \dots, i_{lo} - 1;$$

$$\mathbf{rscale}[j-1] = \hat{d}_j, \text{ for } j = i_{lo}, \dots, i_{hi};$$

$$\mathbf{rscale}[j-1] = P_j, \text{ for } j = i_{hi} + 1, \dots, n.$$

The order in which the interchanges are made is  $n$  to  $i_{hi} + 1$ , then 1 to  $i_{lo} - 1$ .

12: **fail** – NagError \* *Input/Output*

The NAG error argument (see Section 2.7 in How to Use the NAG Library and its Documentation).

## 6 Error Indicators and Warnings

### NE\_ALLOC\_FAIL

Dynamic memory allocation failed.

See Section 2.3.1.2 in How to Use the NAG Library and its Documentation for further information.

**NE\_BAD\_PARAM**

On entry, argument  $\langle value \rangle$  had an illegal value.

**NE\_INT**

On entry,  $\mathbf{n} = \langle value \rangle$ .

Constraint:  $\mathbf{n} \geq 0$ .

On entry,  $\mathbf{pda} = \langle value \rangle$ .

Constraint:  $\mathbf{pda} > 0$ .

On entry,  $\mathbf{pdb} = \langle value \rangle$ .

Constraint:  $\mathbf{pdb} > 0$ .

**NE\_INT\_2**

On entry,  $\mathbf{pda} = \langle value \rangle$  and  $\mathbf{n} = \langle value \rangle$ .

Constraint:  $\mathbf{pda} \geq \max(1, \mathbf{n})$ .

On entry,  $\mathbf{pdb} = \langle value \rangle$  and  $\mathbf{n} = \langle value \rangle$ .

Constraint:  $\mathbf{pdb} \geq \max(1, \mathbf{n})$ .

**NE\_INTERNAL\_ERROR**

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG.

See Section 2.7.6 in How to Use the NAG Library and its Documentation for further information.

**NE\_NO\_LICENCE**

Your licence key may have expired or may not have been installed correctly.

See Section 2.7.5 in How to Use the NAG Library and its Documentation for further information.

**7 Accuracy**

The errors are negligible, compared to those in subsequent computations.

**8 Parallelism and Performance**

nag\_zggbal (f08wvc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the x06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users' Note for your implementation for any additional implementation-specific information.

**9 Further Comments**

nag\_zggbal (f08wvc) is usually the first step in computing the complex generalized eigenvalue problem but it is an optional step. The matrix  $B$  is reduced to the triangular form using the  $QR$  factorization function nag\_zgeqrf (f08asc) and the unitary transformation  $Q$  is applied to the matrix  $A$  by calling nag\_zunmqr (f08auc). This is followed by nag\_zgghrd (f08wsc) which reduces the matrix pair into the generalized Hessenberg form.

If the matrix pair  $(A, B)$  is balanced by this function, then any generalized eigenvectors computed subsequently are eigenvectors of the balanced matrix pair. In that case, to compute the generalized eigenvectors of the original matrix, nag\_zggbak (f08wvc) must be called.

The total number of floating-point operations is approximately proportional to  $n^2$ .

The real analogue of this function is nag\_dggbal (f08whc).

## **10 Example**

See Section 10 in nag\_zhgeqz (f08xsc) and nag\_ztgevc (f08yxc).
